

Blockchain could play an important role in future agriculture and food security

By Abdul-Rahim Abdulai, Carling Bieg, Evan Fraser and Sarah Marquis

16 Apr 2021

Global food supply chains proved brittle during the Covid-19 pandemic, leading for calls to boost the resilience of global food supply chains through improved efficiency in production, distribution and consumption of nutritious food. How could technologies like blockchain that provide data to producers, distributors and consumers be part of the solution?

Technological advances can help manage more efficient, sustainable and accountable farming practices. (Shutterstock)

Big data applications may present opportunities to address inefficiencies from farm to table and improve global food security.

Blockchain, [a linked decentralized database that stores auditable data throughout entire supply chains](#), may change the game for food producers across the globe.

The Food and Agriculture Organization reviews challenges and opportunities for agrifood systems.

With global-scale food systems such as seafood, [nearly 40 per cent of which is traded globally](#), data transparency and traceability through technologies like blockchain are important for socially and environmentally conscious decision making and [to facilitate trust among stakeholders](#).

Gathering information

Blockchain technologies can be used to consolidate information on the quality of the seed, track how crops grow and record the journey once it leaves the farm. In Canada, for example, [Grain Discovery](#) - an online blockchain marketplace - is an example of data being leveraged by those involved in the food system to grow and market globally competitive crops.

The data could enhance transparency in supply chains by providing immutable records from production to consumption. Such data have the potential to facilitate information transfer throughout every step of the supply chain. And if blockchains are implemented with proper validation, it can prevent illegal and unethical production and distribution that undermines sustainability and community food security.

For example, [Wal-Mart, Tsinghua University and IBM's chain-based food traceability platforms have aided in tracing pork and mango in China and the U.S. respectively](#), with positive results in creating trust and transparency in the supply chains.

This transparency also means consumers could make informed decisions to protect vulnerable producers and the environment. Access to product data may allow consumers to reward producers who employ good practices, such as rural smallholder farmers and fishermen who are among [the most food-insecure groups](#).

Tracking pathways

Currently, there is little evidence supporting the claim that blockchain and big data technologies are contributing to global food security. Even though the average farm is projected to generate [4.1 million data points by 2050](#), up from 190,000 data points in 2014, increases in global food security have not been impressive.

Part of the challenge is how blockchains have been implemented until now. The corporate control of blockchains and big data platforms could even undermine food security.

For example, IBM and Walmart have teamed up to track produce from farm to fork. Producers and processors along the supply chain are required to input information into IBM's blockchain for the process to be entirely transparent to consumers.

However, there is [skepticism around IBM's definition of blockchain](#), as privately owned blockchains can be [tampered with more easily](#) and are less secure. This is because security of private blockchains are still highly dependent on permissions and controls set by private organizations.

Corporate-owned, [centralized databases of information do not meet the traditional definition of a blockchain, which is based on democracy and trust](#).

Traditional blockchains are decentralized and democratized in order to ensure trust between users. Corporate control of supply chain information could also [leave out small-scale farmers](#) that lack the required size, scale and technological know-how to participate. This division between large and small food producers can contribute to global food insecurity, and many researchers believe that [small, as well as large farms, are required to feed the world's growing population](#).

Data and food futures

Before blockchain and other data technologies can help address food security, [a number of challenges need to be addressed](#).

The implementation of blockchains must be decentralised to include small farmers and rural people. This will enable sustainable and equitable food systems and allow consumers to make informed decisions.

However, as blockchains place additional responsibility on the end users, challenges such as limited digital literacy among the world's poor and infrastructure constraints may undermine true decentralisation.

Also, they must be integrated into broader food security promotion strategies to make them sensitive to social and environmental values critical to tackling food insecurity among diverse groups.

The untapped potential of harnessing big data through a transparent and decentralized food distribution system may support sustainable food production and provide accountability for food production.

This is crucial for efficient food systems and food security in the future. But it is important that these innovations are deployed equitably so that all stakeholders along the value chain may benefit.
